

SEQUENCE-PRESERVING DEEP-PACKET PROCESSING IN A MULTIPROCESSOR SYSTEM

Abstract of the Disclosure

Packets or frames of data may be compressed, encrypted/decrypted, filtered, classified,
5 searched or subjected to other deep-packet processing operations before being distributed
through the internet. The microprocessor system and method of the present invention provide
for the orderly processing of such data packets without disrupting or changing the sequence in
which the data is intended to be transmitted to its destination. This is achieved by receiving
frames into an input buffer for processing. Associated with this input buffer is a unit for
10 determining the operation to be performed on each frame. An arbitrator assigns each frame to
a processing core engine. An output buffer collects the processed frames, and a sequencer
forwards the processed frames from the output buffer to their destination in the same order as
received by the input/output buffer. Maintaining the sequence of data transmission is
particularly useful in voice transmission, such as videos and movies.
